(57) **ABSTRACT**

A watchband with integrated electronics designed to be attachable to any standard mechanical or digital timepiece. The watchband has a flexible circuit board sandwiched between layers of watchband material, allowing for the flexibility of a normal watchband with the electronics capability of a mobile computer and fitness tracker. The watchband has an embedded heart rate sensor, body temperature sensor, ambient temperature sensor, vibration generator, inertial sensors, and wireless communication device. The watchband is powered by a rechargeable battery, which is recharged using a charging port that can be connected to a battery charger.

## WATCHBAND WITH INTEGRATED ELECTRONICS

### FIELD OF THE INVENTION

The present device relates to a watchband that, in addition to being able to be attached to any mechanical or digital timepiece, has integrated electronics capable of diverse functionalities and interactions with a multitude of digital devices.

### BACKGROUND

Wearable computing has become a prevalent step forward in the progress of technology. Consumers are searching for greater and greater opportunities to integrate technology with everyday wearable items such as glasses, necklaces, and bracelets. Many products on the market today connect to a user's mobile device and allow for the pushing of notifications, answering emails and text messages, as well as the basic functions of keeping time and screening calls.

An additional trend being seen is the rise of digital fitness trackers. Fitness tracking devices are commonly worn around the wrist, neck, or on the ear, and combine specialized sensors to detect motion, steps taken, and heart rate. More advanced models can combine sensors with computing algorithms to provide a user with respiration rates, calories burned, sleep cycle analyses, and general metabolic information. Many of the fitness trackers currently on the market allow for a user to upload and share fitness data to a computer or a social network, allowing for the tracking of a user's fitness data over time.

In spite of the rising popularity of both wearable computers and fitness trackers, the wristwatch still remains a popular fashion accessory. Wristwatches can be a triumph of mechanical design, having hundreds, even thousands, of moving parts. Many luxury watches have the mechanical ability to display far more than the hours and the minutes; extra features, such as tracking eclipses or planetary motions, are termed "complications" in horology, the study of watches and clocks. Timepieces convey status and wealth, fashion and taste, and a sense of punctuality. And while many of the above mentioned wearable computers or fitness trackers seek to emulate clocks or watches on their central displays, none can replicate the mechanical intricacy or aesthetic elegance of a luxury timepiece. What is needed is a watchband with integrated electronics that can provide the same functionality of a wearable computer or fitness tracker, but able to be attached to a user's desired mechanical or digital timepiece such that the timepiece's aesthetics and functionality are not impaired.

### SUMMARY OF THE INVENTION

It is an aspect of the disclosure to provide an improved watchband with integrated electronics. These together with other aspects and advantages, which will be subsequently apparent, reside in the details of construction and operation as more fully hereinafter described and claimed, reference being had to the accompanying drawings forming a part hereof, wherein like numerals refer to like parts throughout.

### A BRIEF DESCRIPTION OF THE DRAWINGS

Further features and advantages of the present device, as well as the structure and operation of various embodiments of the present device, will become apparent and more readily

2

appreciated from the following description of the preferred embodiments, taken in conjunction with the accompanying drawings of which:

FIG. 1 is an exploded view of a watchband with integrated electronics with a timepiece, according to an embodiment.

FIG. 2 is an exploded view of a watchband with integrated electronics with a timepiece, according to an alternate embodiment.

FIG. 3 is a top view of a watchband with integrated electronics without a timepiece, according to an embodiment.

FIG. 4 is a bottom view of a watchband with integrated electronics without a timepiece, according to an embodiment.

FIG. 5A is a perspective view of a watchband with integrated electronics having a timepiece attached, according to an embodiment.

FIG. 5B is a perspective view of a watchband with integrated electronics having a timepiece attached, according to an alternate embodiment.

FIG. 6 is a top view of a watchband with integrated electronics with a timepiece, according to an embodiment.

FIG. 7 is a side view of a watchband with integrated electronics with a timepiece, according to an embodiment.

FIG. 8 is a block diagram illustrating the features and peripherals of a watchband with integrated electronics, according to an embodiment.

FIG. 9 is a flowchart diagram illustrating the functional components of a heart rate sensor, according to an embodiment.

FIG. 10A is an exploded view of a watchband with integrated electronics with a timepiece, according to an alternate embodiment.

FIG. 10B is an exploded view of a watchband with integrated electronics with a timepiece, according to an alternate embodiment.

FIG. 11 is a top view of a watchband with integrated electronics without a timepiece, according to an alternate embodiment.

FIG. 12 is a bottom view of a watchband with integrated electronics without a timepiece, according to an alternate embodiment.

FIG. 13A is a top view of a flexible circuit board for a watchband with integrated electronics, according to an alternate embodiment.

FIG. 13B is a top view of a flexible circuit board for a watchband with integrated electronics, according to an alternate embodiment.

FIG. 13C is a top view of a flexible circuit board for a watchband with integrated electronics, according to an alternate embodiment.

FIG. 13D is a top view of a flexible circuit board for a watchband with integrated electronics, according to an alternate embodiment.

### DETAILED DESCRIPTION

The present invention relates to a watchband with integrated electronics. Specifically, the invention seeks to emulate the functionality of wearable computers and personal fitness trackers, but allows a user to continue to use a mechanical (analog) or digital timepiece. Thus, the integrated electronics can be entirely located in the watchband itself, with the mechanical or digital timepiece being interchangeable according to the user's preference without a loss of functionality or performance. In a primary embodiment, the watchband's integrated electronics can be configured to wirelessly interact with a user's mobile device, which can include

smartphones, PDAs, personal computers, vehicles, or other electronic devices with wireless or cellular capabilities.

The watchband (and its parts) can be created using a variety of watchband materials, including, but not limited to, leather, silicone, metal, fabric, plastic, rubber, composite materials, or a combination thereof. The watchband can be constructed using a body-contacting layer of watchband material, an outer layer of watchband material, and, in some embodiments, one or more timepiece connection layers of watchband material. The watchband material layers can be connected using needlepoint, glue, heat bonding, adhesives, or other connection means. In addition to the internal electronics, the watchband can include a tang-type clasp with tang and tang holes for adjustment on the wrist, along with excess strap loops to secure any extra portion of the strap after the user puts on the watch. Alternate embodiments of the wristband can have a deployant-type clasp, either inside style or outside style, or a buckle clasp in place of the tang-type clasp.

By using the layered construction technique, a flexible circuit board can be placed in between the body-contacting and outer layers of the watchband material, such that the flexible circuit board, and its associated electronics, can remain safe from weather and wear. A flexible circuit board can be a printed circuit board that allows for the same level of electrical connection fidelity between components as a regular circuit board, but can be manufactured out of materials such as polyimide, polyether ether ketone, polyester, polyethylene naphthalate, polyetherimide, or copolymer polyimide films, allowing for the circuit board to be able to bend and flex dramatically more than a regular surface board would allow whilst still retaining those electrical connections. The flexible circuit board can have preprinted connection points for the soldering of components for ease of manufacturing. Embedded on the flexible circuit board can be a variety of sensors devoted to the measurement of various bodily functions, health criteria, and device information. These sensors can be connected to a central microprocessor, which can be used as the computational hub of the watchband.

In an embodiment, the watchband can have an integrated heart rate sensor connected to the flexible circuit board. The heart rate sensor can be a photoplethysmograph optical sensor, which uses a light-emitting diode (LED) and a photodiode in conjunction in order to measure changes in blood flow, similar to the heart rate measurement system described in U.S. Pat. No. 4,258,719, herein incorporated by reference in its entirety. As light shines through the user's skin, its detected intensity changes as the amount of blood flow changes during a heart's systolic and diastolic function. These intensity changes can be read by the photodiode. The photodiode signal can be amplified with a low gain transimpedance amplifier, producing a voltage signal. In an embodiment, the signal gain can be kept low so as to reduce signal noise in the amplification stage. To filter noise, the signal can be passed through a low-pass second order filter, followed by a low-cutoff frequency high-pass filter, and followed again by a second low-pass filter to remove any remaining noise. All filters can be built with operational amplifiers (op-amps). In order for the heart rate monitor to function, a LED hole and a photodiode hole can be made on the body-contacting layer of watchband material.

In addition to the heart rate sensor, the watchband can have two temperature sensors embedded on the flexible circuit board. One temperature sensor can lie on the side of the watchband facing the user's skin, and be used to continuously monitor the user's body surface temperature. The second sensor can lie on the side of the watchband facing opposite the user's wrist, and be used to continuously monitor the ambient

temperature. In order for the temperature sensors to function, a body temperature sensor hole can be cut into the body-contacting layer of watchband material, and an ambient temperature sensor hole can be cut into the outer layer of watchband material. If needed, an ambient temperature sensor hole can also be cut into the timepiece connection layer of watchband material. Both temperature sensors can be thermocouples, thermistors, semiconductors, digital integrated sensors, or a combination thereof.

The watchband can have a wireless communication device for communications between the watchband and the user's mobile device. The user's mobile device can include a cellular phone, personal computer, tablet, medical device, internet router, integrated telemetry device, or other wirelessly communicating device. The wireless communication device can be a Bluetooth transceiver, an IEEE 802.11 transceiver, radio transceiver, or other wireless communication mechanism. The wireless communication device can have a small physical profile, low power consumption, and durable construction.

The watchband can be powered by a rechargeable battery. The rechargeable battery can be lithium-ion, lithium-polymer, nickel-cadmium, nickel-hydrogen, nickel-zinc, thin film lithium, or other metallic combination thereof. The battery can be small in profile, and able to hold a charge for an extended period of time. The battery can be recharged using a battery charger, which can interact directly with the watchband at a charging port, which can be a series of metal contacts. The battery charger can be connected to the charging port using magnets, physical clasps, or wireless induction. To keep the charging port and the metal contacts accessible, a charging port hole can be cut on the body-contacting or outer layer of the watchband material. In order to maintain performance of the watchband at various states of charge, a buck-boost DC-DC converter can be used to keep the output voltage constant. Alternatively, a power management circuit (PMIC) can be included in the watchband in place of the buck-boost DC-DC converter, which can regulate battery charging, voltages rates, activation control, and other features.

Any standard mechanical or digital timepiece can be used with the watchband. The timepiece can be held in place by timepiece joints hidden within connection channels located on the timepiece connection layer of watchband material. The timepiece joints can be hollow tubes, with sufficient diameter to admit a screw or pin. The timepiece, which can have mounting supports, can fit such that the timepiece connection channels, having the timepiece joints inside, align with the mounting supports. The user can add the screws or pins in order to secure the timepiece to the timepiece joints and the timepiece connection layer. In order to change out the timepiece, the user would remove the screws or pins, replace the timepiece with an alternate timepiece, and re-add the screws or pins.

FIG. 1 is an exploded view of a watchband with integrated electronics with a timepiece 300, according to an embodiment. The watchband can be created using a variety of watchband materials, including, but not limited to, leather, silicone, metal, fabric, plastic, rubber, composite materials, or a combination thereof. The watchband can be constructed in a layered manner, having a body-contacting layer of watchband material 350, an outer layer of watchband material 351, a first timepiece connection layer 352 and a second timepiece connection layer 353 of watchband material. The watchband material layers 350, 351, 352, 353 can each be different materials, and can be connected using needlepoint, glue, heat bonding, adhesives, or other connection means. The body

5

connecting layer **350** can be connected to the outer layer **351** with the flexible circuit board placed in between, while the first timepiece connection layer **352** and the second timepiece connection layer **353** can be connected on top of the outer layer **351**. The first timepiece connection layer **352** and the second timepiece connection layer **353** can be connected at a distance of a timepiece length. A timepiece length can be the space needed to admit a standard analog or digital timepiece. Alternatively, the watchband material layers can be molded as a single piece, with the flexible circuit board **310** embedded within. In addition to the internal electronics, the watchband can include a tang-type clasp **104** with tang **105** and tang holes **103** for adjustment on the user's wrist (not shown), along with excess strap loops **106** to secure any extra portion of the strap after the user puts on the assembled watch (not shown). Alternate embodiments of the wristband can have a deployant-type clasp (not shown), either inside style or outside style, or a buckle clasp (not shown) in place of the tang-type clasp **104**.

By using the layered construction technique, a flexible circuit board **310** can be sandwiched and sealed in between the body-contacting layer **350** and outer layer **351** of the watchband material, such that the flexible circuit board **310** and its associated electronics can be protected from weather and wear. The flexible circuit board **310** can be a printed circuit board that allows for the same level of electrical connection fidelity between components as a regular circuit board, but can be manufactured out of materials allowing for the circuit board to be able to bend and flex dramatically more than a regular surface board would allow whilst still retaining those electrical connections. The flexible circuit board **310** can have preprinted connection points for the soldering of components for ease of manufacturing. Embedded on the flexible circuit board **310** can be a variety of sensors devoted to the measurement of various bodily functions, health criteria, and device information. These sensors can be connected to a central microprocessor (not shown), which can be used as the computational hub of the watchband.

In an embodiment, the watchband can have an integrated heart rate sensor connected to the flexible circuit board **310**. The heart rate sensor can be a photoplethysmograph optical sensor, which uses a light-emitting diode (LED) **152** and a photodiode **153** in conjunction in order to measure changes in the user's blood flow. As light from the LED **152** shines onto the user's skin, its detected intensity changes as the amount of blood flow changes during the heart's systolic and diastolic function. These intensity changes can be read by the photodiode **153**. The photodiode **153** signal can be amplified with a low gain transimpedance amplifier (not shown), producing a voltage signal. In an embodiment, the signal gain can be kept low so as to reduce signal noise in the amplification stage. To filter noise, the signal can be passed through a low-pass second order filter (not shown), followed by a low-cutoff frequency high-pass filter (not shown), and followed again by a second low-pass filter (not shown) to remove any remaining noise. The amount and order of filters can be changed to further alter the signal. All filters can be built with operational amplifiers (op-amps). In order for the heart rate monitor to function, a LED hole **364** and a photodiode hole **365** can be made on the body-contacting layer **350** of watchband material.

In addition to the heart rate sensor, the watchband can have two temperature sensors, a body temperature sensor **151** and an ambient temperature sensor **150**, embedded on the flexible circuit board **310**. The body temperature sensor **151** can face the side of the watchband facing the user's skin and be used to continuously monitor the user's body surface temperature.

6

The ambient temperature sensor **150** can face the side of the watchband facing the world, and be used to continuously monitor the ambient temperature. In order for the temperature sensors **150**, **151** to function, a body temperature sensor hole **303** can be cut into the body-contacting layer **350** of watchband material, and an ambient temperature sensor hole **360** can be cut into the outer layer of watchband material **351**. If needed, an ambient temperature sensor hole **361** can also be cut into the second timepiece connection layer **361** of watchband material. When constructed, the ambient sensor holes **360**, **361** can be aligned such that the ambient temperature sensor is exposed to the ambient air. Both temperature sensors **150**, **151** can be thermocouples, thermistors, semiconductors, digital integrated sensors, or a combination thereof.

The watchband can have a wireless communication device **155** for communications between the watchband and a user's mobile device (not shown). The user's mobile device (not shown) can include a cellular phone, personal computer, tablet, medical device, internet router, integrated telemetry device, or other wirelessly communicating device. The wireless communication device **155** can be a Bluetooth transceiver, an IEEE 802.11 transceiver, radio transceiver, or other wireless communication mechanism. The wireless communication device **155** can have a small physical profile, low power consumption, and durable construction.

The watchband can be powered by a rechargeable battery **156**, which can also be sandwiched between the body-contacting layer **350** and the outer layer **351** of watchband material. The rechargeable battery **156** can be lithium-ion, lithium-polymer, nickel-cadmium, nickel-hydrogen, nickel-zinc, thin film lithium, or other metallic combination thereof. The battery **156** can be small in profile, and able to hold a charge for an extended period of time. The battery **156** can be attached to the flexible circuit board **310** by a series of metallic battery connections **157**. The battery **156** can be recharged using a battery charger (not shown), which can interact directly with the watchband at a charging port **154**, which can be a series of metal contacts. The battery charger can be connected to the charging port using magnets, physical clasps, or wireless induction. To keep the charging port's **154** the metal contacts accessible, a charging port hole **362** can be cut on the body-contacting **350** or outer layer **351** of the watchband material. In order to maintain performance of the watchband at various states of charge, a buck-boost DC-DC converter (not shown) can be used to keep the output voltage constant. Alternatively, a power management circuit (PMIC) can be included in the watchband in place of the buck-boost DC-DC converter, which can regulate battery charging, voltages rates, activation control, and other features.

Any standard mechanical or digital timepiece **300** can be used with the watchband. The timepiece **300** can be held in place by timepiece joints **301** hidden within connection channels **302** located on the first connection layer **352** and second connection layer **353** of watchband material. The timepiece joints **301** can be hollow tubes, with sufficient diameter to admit a screw or pin (not shown), and can be made from plastic or metal. The timepiece **300**, which can have mounting supports **340** having mounting holes **341**, can fit such that the timepiece connection channels **302**, having the timepiece joints **301** inside, align with the mounting support **340** and the mounting holes **341**. The user can add the screws or pins to the mounting holes **341** in order to secure the timepiece **300** to the timepiece joints **301** and the timepiece connection layers **352**, **353**. In order to change out the timepiece **300**, the user would remove the screws or pins from the mounting holes **341**,

7

replace the timepiece **300** with an alternate timepiece (not shown), and re-add the screws or pins to the alternate mounting holes (not shown).

FIG. 2 is an exploded view of a watchband with integrated electronics with a timepiece, according to an alternate embodiment. In the alternate embodiment, the first timepiece connection layer **352** and second timepiece connection layer **353** of watchband material are molded as part of the outer layer **351** of watchband material, as opposed to the first embodiment shown in FIG. 1 where the first timepiece connection layer **352** and second timepiece connection layer **353** are separate layers that can be attached to the outer layer **351** of watchband material. This melding can occur when the watchband is made out of a molded material, such as plastics, silicone, or rubber. Because the second connecting layer **353** is melded with the outer layer **351** of watchband material, only a single ambient temperature sensor hole **360** is needed to be cut into the outer layer **351** in order for the ambient temperature sensor **150** to function properly. All other elements of the watchband can remain the same. The flexible circuit board **310**, with its embedded sensors and connections, can sandwich between the body-contacting layer **350** and outer layer **351** of watchband material.

FIG. 3 is a top view of a watchband with integrated electronics without a timepiece, according to an embodiment. The first timepiece connection layer **352** and the second timepiece connection layer **353** of watchband material can be connected atop the outer layer **351** of watchband material, and the outer layer **351** can be connected to the body-contacting layer (not shown) such that the edges of each layer are aligned. The flexible circuit board (not shown) is not visible when the watchband is assembled. The tang holes **103** can penetrate all three watchband material layers, in order for the tang clasp **104** tang **105** to fully secure the watchband **100** on a user's wrist. A portion of the outer layer **351** can be left uncovered by the first connection layer **352** and the second connection layer **353**, with the portion being large enough to admit the length of a standard timepiece (a timepiece length). The timepiece (not shown) can be placed between the first connection layer **352** and the second connection layer **353** such that the timepiece (not shown) covers the exposed portion of the outer layer **351** and faces outwards. Also visible is the ambient temperature sensor **150**, which can be exposed to the ambient atmosphere through the ambient temperature sensor hole **361** cut into the second connection layer **363**.

FIG. 4 is a bottom view of a watchband with integrated electronics without a timepiece, according to an embodiment. As in the top view, the first timepiece connection layer (not shown) and the second timepiece connection layer (not shown) of watchband material can be connected atop the outer layer (not shown) of watchband material, and the outer layer (not shown) can be connected to the body-contacting layer **350** such that the edges of each layer are aligned. From this view, the body temperature sensor **151**, heart rate sensor LED **152**, heart rate sensor photodiode **153**, and charging port **154** can be seen through the body temperature sensor hole **303**, LED hole **364**, photodiode hole **365**, and charging port hole **362**, respectively.

FIG. 5A is a perspective view of a watchband with integrated electronics **100** having a timepiece **300** attached, according to an embodiment. In this view, the body-contacting layer **350**, outer layer **351**, and timepiece connection layers **352**, **353** can be assembled such that the flexible circuit board (not shown) is not visible. From this view, the ambient temperature sensor **150** can be obliquely visible through the ambient temperature sensor hole **361**.

8

Any standard mechanical or digital timepiece **300** can be used with the watchband. The timepiece **300** can be held in place by timepiece joints **301** hidden within connection channels **302** located on the first connection layer **352** and second connection layer **353** of watchband material. The timepiece joints **301** can be hollow tubes, with sufficient diameter to admit a screw or pin (not shown), and can be made from plastic or metal. The timepiece **300**, which can have mounting supports **340** having mounting holes **341**, can fit such that the timepiece connection channels **302**, having the timepiece joints **301** inside, align with the mounting support **340** and the mounting holes **341**. The user can add the screws or pins to the mounting holes **341** in order to secure the timepiece **300** to the timepiece joints **301** and the timepiece connection layers **352**, **353**. In order to change out the timepiece **300**, the user would remove the screws or pins from the mounting holes **341**, replace the timepiece **300** with an alternate timepiece (not shown), and re-add the screws or pins to the alternate mounting holes (not shown).

FIG. 5B is a perspective view of a watchband with integrated electronics having a timepiece **300** attached, according to an alternate embodiment. In an alternate embodiment, the body contacting layer **1050** and the outer layer **1051** can both have a bulged middle that can occlude the timepiece **300** when seen from the bottom. The function of the various peripherals (heart rate sensor, temperature sensors, air quality sensor, etc.) are the same as in other embodiments. In an alternate embodiment, the ambient temperature sensor **150** is located further away from the timepiece **300**, in order to provide a more accurate reading of the ambient temperature.

FIG. 6 is a top view of a watchband with integrated electronics with a timepiece, according to an embodiment. In this view, the timepiece **300** can cover the previously exposed portion of the outer layer **351** of watchband material. The first timepiece connection layer **352** and second timepiece connection layer **353** can be spaced such that the timepiece **300** is easily admitted between the two connection layers **351**, **352**. If the timepiece **300** is replaced with an alternate timepiece (not shown) that is larger in length, the connection layers **351**, **352** are flexible, allowing their ends to bend backward in order to admit the longer length of the alternate timepiece. Visible from this view can be the ambient temperature sensor **150**.

FIG. 7 is a side view of a watchband with integrated electronics with a timepiece, according to an embodiment. This view further illustrates how the timepiece **300** can cover the previously exposed portion of the outer layer **351** of watchband material. As the body-contacting layer **350** and outer layer **351** are assembled in this view, the flexible circuit board (not shown), as well as the majority of the embedded circuitry, is not visible. However, the ambient temperature sensor **150** can be seen through the ambient temperature sensor hole **361**.

FIG. 8 is a block diagram illustrating the features and peripherals of a watchband with integrated electronics, according to an embodiment. The watchband's sensors and functionality can primarily be controlled by a microprocessor **800** having the capability to interact with the various sensors, as well as input and output communication information. The microprocessor **800** can draw a small amount of power, in order for the watchband to avoid frequent recharging. All peripherals can selectively communicate with the microprocessor **800**. The microprocessor **800** can selectively activate or deactivate the watchband peripherals depending on the requirements of the user. A random access memory (RAM) module **850** can store all detected values from the peripherals before transmittal to the mobile device. A read-only memory

(ROM) module **851** can store the watchband's basic input-output system (BIOS) and operating software (OS) needed for standard operations.

In addition to the heart rate sensor **801**, the watchband can have two temperature sensors, a body temperature sensor **151** and an ambient temperature sensor **150**, embedded on the flexible circuit board (not shown). The body temperature sensor **151** can face the side of the watchband facing the user's skin and be used to continuously monitor the user's body surface temperature. The ambient temperature sensor **150** can face the side of the watchband facing the world, and be used to continuously monitor the ambient temperature. Both temperature sensors **150**, **151** can be thermocouples, thermistors, or a combination thereof.

The watchband can have a wireless communication device **155** for communications between the watchband and a user's mobile device **806**. The user's mobile device **806** can include a cellular phone, personal computer, tablet, medical device, internet router, integrated telemetry device, or other wirelessly communicating device. The wireless communication device **155** can be a Bluetooth transceiver, an IEEE 802.11 transceiver, radio transceiver, or other wireless communication mechanism. The wireless communication device **155** can have a small physical profile, low power consumption, and durable construction. The wireless communication device can additionally include a near field communication (NFC) chip, allowing for communication between the watchband and mobile device **806** when placed in close physical proximity. The mobile device **806** can run an application that can receive, display, and store data from all peripheral devices on the watchband.

The watchband can be powered by a rechargeable battery **156**. The rechargeable battery **156** can be lithium-ion, lithium-polymer, nickel-cadmium, nickel-hydrogen, nickel-zinc, thin film lithium, or other metallic combination thereof. The battery **156** can be small in profile, and able to hold a charge for an extended period of time. The battery **156** can be attached to the flexible circuit board by a series of metallic battery connections (not shown). The battery **156** can be recharged using a battery charger **803**, which can interact directly with the watchband at a charging port (not shown), which can be a series of metal contacts. The battery charger can be connected to the charging port using magnets, physical clasps, or wireless induction. In order to maintain performance of the watchband at various states of charge, a buck-boost DC-DC converter **802** can be used to keep the output voltage constant. Alternatively, a power management circuit (PMIC) **802** can be included in the watchband in place of the buck-boost DC-DC converter, which can regulate battery charging, voltages rates, activation control, and other features.

The watchband can also contain a set of inertial sensors **805**, including an accelerometer, gyroscope, and compass. The inertial sensors **805** can be devices used to determine the watchband's position and orientation, and whether or not the watchband is being subjected to any acceleration forces along any of the major three axis of movement. The inertial sensors **805** can allow the watchband to act as a pedometer and a physical activity measurement tool. Additionally, the inertial sensors **805** can be tied into the watchband's power management software, allowing for the watchband to enter a low power state mode when not in use and to be woken when movement is again detected. Similarly, the inertial sensors **805** can be used to increase another watchband sensor's accuracy. For example, if too much motion activity makes readings from the heart rate sensor **801** unreliable, the measure-

ments from the inertial sensors can trigger a shutdown of the heart rate sensor **801** until such motion has ceased.

The watchband can also contain a vibration generator **804** that vibrates when power is applied. The vibration generator **804** can be a small piezoelectric crystal that vibrates under power. The vibration generator **804** can be controlled by a metal-oxide-semiconductor field-effect transistor (MOS-FET), which can be activated by the microcontroller **800** to convey customizable and specific tactile notification to the user, such as informing if the device's power is turned on or off, incoming phone calls, emails, or text messages, or if a pre-set heart rate or temperature is being exceeded.

The watchband can also contain an air quality sensor **812** that can be used to detect the ambient humidity and air quality, or can be used to determine levels of pollutants in the atmosphere, such as smog, radon, carbon monoxide, or other contaminants. The air quality sensor **812** can be chemical or electrical.

The watchband can also contain an alert device **810** that can be configured to contact a predesignated emergency service through wireless communication when activated. The emergency service can be 911, a private security service, fire service, ambulance service, or, in the case of a medical facility, an emergency page service for the health care professionals. The alert device can be a depressible button or switch, but can be constructed such that the device is not easily toggled, to prevent false alarms.

FIG. 9 is a flowchart diagram illustrating the functional components of a heart rate sensor **801**, according to an embodiment. In an embodiment, the watchband can have an integrated heart rate sensor **801** connected to the flexible circuit board (not shown). The heart rate sensor **801** can be a photoplethysmograph optical sensor, which uses a light-emitting diode (LED) **152** and a photodiode **153** in conjunction in order to measure changes in the user's blood flow. As light from the LED **152** shines onto the user's arm **905**, its detected intensity changes as the amount of blood flow changes during the user's heart's systolic and diastolic function. These intensity changes can be read by the photodiode **153**. The photodiode **153** signal can be amplified with a low gain transimpedance amplifier **901**, producing a voltage signal. In an embodiment, the signal gain can be kept low so as to reduce signal noise in the amplification stage. To filter noise, the signal can be passed through a low-pass second order filter **902**, followed by a low-cutoff frequency high-pass filter **903**, and followed again by a second low-pass filter **904** to remove any remaining noise, at which point the filtered signal can be sent to the microcontroller **800**. The order and amount of filters can be altered to alter the signal output of the heart rate sensor **801**, and is not limited to the description provided above. All filters can be built with operational amplifiers (op-amps).

FIG. 10A is an exploded view of a watchband with integrated electronics with a timepiece, according to an alternate embodiment. In an alternate embodiment, the body contacting layer **1050** and the outer layer **1051** can both have a bulged middle **1000** that can occlude the timepiece **300** when seen from the bottom. The flexible circuit board **1010** can be formed in a bulged geometry to mimic the geometry of the body contacting layer **1050** and the outer layer **1051**. The body temperature sensor **151**, LED **152**, and photodiode **153** can function similarly in all embodiments, but can be placed on the flexible circuit board **1010** to fully take advantage of the board's **1010** geometry. Likewise, the body temperature sensor hole **1065**, LED hole **1064**, and photodiode hole **1063** can all be cut into the body contacting layer **1050** of watch-

11

band material to match their respective sensors' positions on the flexible circuit board **1010**.

The flexible circuit board **1010** can have flexible connectors **1302**, which allow for more flexibility between the flexible circuit board **1010**, and the one or more rechargeable batteries **156** that can power the flexible circuit board **1010** through the one or more battery connections **157**. The flexible circuit board **1010** can be made of a rigid circuit material **1301**, which can necessitate its placement entirely between the bulged middles **1000** of the outer layer **1051** and the body contacting layer **1050** of watchband material, placing the flexible circuit board entirely underneath the timepiece **300**, with the one or more rechargeable batteries **156** extending outwards within the watchband.

FIG. **10B** is an exploded view of a watchband with integrated electronics with a timepiece, according to an alternate embodiment. In an alternate embodiment, the ambient temperature sensor **150** can be remotely connected to the flexible circuit board **1010** such that the ambient temperature sensor is placed further down the watchband, away from the rest of the peripherals, in order to more accurately measure the ambient air temperature. The watchband can also include a vibration generator **804**, which can generate vibrational pulses based on the commands sent from the microprocessor.

FIG. **11** is a top view of a watchband with integrated electronics without a timepiece, according to an embodiment. In an alternate embodiment, both the outer layer **1051** and body contacting layer (not shown) of watchband material can be created with a bulged middle **1000** such that there can be a greater amount of surface area covered by the layers of watchband material. The position of the ambient temperature sensor **150**, along with the ambient temperature sensor hole **360**, can remain the same as in other embodiments.

FIG. **12** is a bottom view of a watchband with integrated electronics without a timepiece, according to an embodiment. In an alternate embodiment, both the outer layer (not shown) and body contacting layer **1050** of watchband material can be created with a bulged middle **1000** such that there can be a greater amount of surface area covered by the layers of watchband material. The body temperature sensor **151**, LED **152**, and photodiode **153** can be positioned linearly, or in any desired configuration. The position of the metal contacts **154** can remain the same as in other embodiments.

FIG. **13A** is a top view of a flexible circuit board for a watchband with integrated electronics, according to an embodiment. The flexible circuit board **310** can be a printed circuit board that allows for the same level of electrical connection fidelity between components as a regular circuit board, but can be manufactured out of materials allowing for the circuit board to be able to bend and flex dramatically more than a regular surface board would allow whilst still retaining those electrical connections. The flexible circuit board **310** can have preprinted connection points for the soldering of components for ease of manufacturing. Embedded on the flexible circuit board **310** can be a variety of sensors devoted to the measurement of various bodily functions, health criteria, and device information. These sensors can be connected to a central microprocessor (not shown), which can be used as the computational hub of the watchband.

In an embodiment, the watchband can have an integrated heart rate sensor connected to the flexible circuit board **310**. The heart rate sensor can be a photoplethysmograph optical sensor, which uses a light-emitting diode (LED) **152** and a photodiode **153** in conjunction in order to measure changes in the user's blood flow. As light from the LED **152** shines onto the user's skin, its detected intensity changes as the amount of blood flow changes during the heart's systolic and diastolic

12

function. These intensity changes can be read by the photodiode **153**. The photodiode **153** signal can be amplified using a series of filters (not shown).

In addition to the heart rate sensor, the watchband can have two temperature sensors, a body temperature sensor **151** and an ambient temperature sensor **150**, embedded on the flexible circuit board **310**. The body temperature sensor **151** can face the side of the watchband facing the user's skin and be used to continuously monitor the user's body surface temperature. The ambient temperature sensor **150** can face the side of the watchband facing the world, and be used to continuously monitor the ambient temperature. Both temperature sensors **150**, **151** can be thermocouples, thermistors, semiconductors, digital integrated sensors, or a combination thereof.

The watchband can have a wireless communication device **155** for communications between the watchband and a user's mobile device (not shown). The wireless communication device **155** can be a Bluetooth transceiver, an IEEE 802.11 transceiver, radio transceiver, or other wireless communication mechanism. The wireless communication device **155** can have a small physical profile, low power consumption, and durable construction.

The watchband can be powered by a rechargeable battery **156**. The rechargeable battery **156** can be lithium-ion, lithium-polymer, nickel-cadmium, nickel-hydrogen, nickel-zinc, thin film lithium, or other metallic combination thereof. The battery **156** can be small in profile, and able to hold a charge for an extended period of time. The battery **156** can be attached to the flexible circuit board **310** by a series of metallic battery connections **157**. The battery **156** can be recharged using a battery charger (not shown), which can interact directly with the watchband at a charging port **154**, which can be a series of metal contacts. The battery charger can be connected to the charging port using magnets, physical clasps, or wireless induction. In order to maintain performance of the watchband at various states of charge, a buck-boost DC-DC converter (not shown) can be used to keep the output voltage constant. Alternatively, a power management circuit (PMIC) can be included in the watchband in place of the buck-boost DC-DC converter, which can regulate battery charging, voltages rates, activation control, and other features.

FIG. **13B** is a top view of a flexible circuit board for a watchband with integrated electronics, according to an alternate embodiment. In an alternate embodiment, the body temperature sensor **151**, LED **152**, photodiode **153**, charging port **154**, wireless communication device **155**, and ambient temperature sensor **150** can all function in the same manner as previous embodiments, but can be placed in differing positions than other embodiments. The flexible circuit board can be divided into sections of rigid circuit material **1301** and flexible connection material **1302**. The modular construction of the alternate flexible circuit board allows for greater flexion around a user's wrist (not shown). All sensors **150**, **151**, **152**, **153**, **154**, **155** can be connected to the watchband on the rigid circuit material **1301**. Additionally, a vibration generator **804** can be connected to the flexible circuit board.

FIG. **13C** is a top view of a flexible circuit board for a watchband with integrated electronics, according to an alternate embodiment. In an alternate embodiment, the body temperature sensor **151**, LED **152**, photodiode **153**, charging port **154**, wireless communication device **155**, and ambient temperature sensor **150** can all function in the same manner as previous embodiments. The flexible circuit board can have a large, rounded section of rigid circuit material **1010**, which can be connected to one or more rechargeable batteries **156** by one or more sections of flexible connection material **1302**.

13

FIG. 13D is a top view of a flexible circuit board for a watchband with integrated electronics, according to an alternate embodiment. In an alternate embodiment, the ambient temperature sensor 150 can be remotely connected to the flexible circuit board 1010 such that the ambient temperature sensor 150 is placed further down the watchband, away from the rest of the peripherals, in order to more accurately measure the ambient air temperature. The watchband can also include a vibration generator 804, which can generate vibrational pulses based on the commands sent from the microprocessor. The alternate embodiment can also include the alert button 810 and air quality sensor 812, which can function in the same manner as described in the other embodiments.

Although the present device has been described in terms of exemplary embodiments, none is limited thereto. Positions of all peripherals (temperature sensors, heart rate sensor, vibration generator, air quality sensor, alert device) can be altered, as well as the amount and location of the various filters, peripherals, and circuitry. No one peripheral is required on any one embodiment, rather, any combination of peripherals is contemplated. Rather, the appended claims should be construed broadly to include other variants and embodiments of the present apparatus, which may be made by those skilled in the art without departing from the scope and range of equivalents of either the apparatus or the methods for using such an apparatus.

This description of the exemplary embodiments is intended to be read in connection with the accompanying drawings, which are to be considered part of the entire written description. In the description, relative terms such as “lower,” “upper,” “horizontal,” “vertical,” “above,” “below,” “up,” “down,” “top,” and “bottom,” as well as derivatives thereof should be construed to refer to the orientation as then described or as shown in the drawing under discussion. These relative terms are for convenience of description and do not require that the apparatus be constructed or operated in a particular orientation. Terms concerning attachments, coupling, and the like, such as “connected,” and “interconnected,” refer to a relationship wherein structures are secured or attached to one another either directly or indirectly through intervening structures, as well as both movable or rigid attachments or relationships, unless expressly described above.

What is claimed is:

1. A watchband with integrated electronics, comprising:
  - a body-contacting layer of watchband material;
  - an outer layer of watchband material;
  - a first timepiece connection layer of watchband material;
  - a second timepiece connection layer of watchband material;
  - a flexible circuit board having a microcontroller and a wireless communication device configured to communicate with a mobile device;
 wherein the body-contacting layer of watchband material is attached to the outer layer of watchband material such that the flexible circuit, connected to a rechargeable battery, is sealed in between the body-contacting layer and the outer layer, and where the first timepiece connection layer and the second timepiece connection layer are attached atop the outer layer at a timepiece length.
2. The watchband as recited in claim 1, wherein:
  - the flexible circuit board further comprises a heart rate sensor having a light-emitting diode and a photodiode; and
  - the body-contacting layer of watchband material further comprises a light-emitting diode hole and a photodiode hole;

14

the flexible circuit board being positioned between the body-contacting layer and outer layer of watchband material such that the light-emitting diode overlaps the light-emitting diode hole and the photodiode overlaps the photodiode hole.

3. The watchband as recited in claim 1, wherein:
  - the flexible circuit board further comprises a body temperature sensor; and
  - the body-contacting layer of watchband material further comprises a body temperature sensor hole;
 the flexible circuit board being positioned between the body-contacting layer and outer layer of watchband material such that the body temperature sensor overlaps the body temperature sensor hole.
4. The watchband as recited in claim 1, wherein:
  - the flexible circuit board further comprises an ambient temperature sensor;
  - the outer layer of watchband material further comprises an ambient temperature sensor hole; and
  - the second timepiece connection layer of watchband material further comprises an ambient temperature sensor hole;
 the flexible circuit board being positioned between the body-contacting layer and outer layer of watchband material such that the ambient temperature sensor overlaps the ambient temperature sensor hole of the outer layer of watchband material and the ambient temperature sensor hole of the second timepiece connection layer of watchband material.
5. The watchband as recited in claim 1, further comprising an ambient temperature sensor, wherein:
  - the ambient temperature sensor remotely connects to the flexible circuit board;
  - the outer layer of watchband material further comprises an ambient temperature sensor hole; and
  - the second timepiece connection layer of watchband material further comprises an ambient temperature sensor hole;
 the ambient temperature sensor being positioned between the body-contacting layer and outer layer of watchband material such that the ambient temperature sensor overlaps the ambient temperature sensor hole of the outer layer of watchband material and the ambient temperature sensor hole of the second timepiece connection layer of watchband material.
6. The watchband as recited in claim 1, further comprising an alert device;
  - the alert device configured to contact an emergency service when activated.
7. The watchband as recited in claim 1, wherein:
  - the flexible circuit board further comprises an air quality sensor;
  - the outer layer of watchband material further comprises an air quality sensor hole; and
  - the second timepiece connection layer of watchband material further comprises an air quality sensor hole;
 the flexible circuit board being positioned between the body-contacting layer and outer layer of watchband material such that air quality sensor overlaps the air quality sensor hole of the outer layer of watchband material and the air quality sensor hole of the second timepiece connection layer of watchband material.
8. The watchband as recited in claim 1, wherein:
  - the flexible circuit board further comprises an inertial sensor configured to detect acceleration in any direction.

## 15

9. The watchband as recited in claim 1, wherein:

the flexible circuit board further comprises a vibration generator configured to produce vibration at the direction of the microcontroller.

10. The watchband as recited in claim 1, further comprising one or more rechargeable battery and a battery charger, wherein:

the flexible circuit board further comprises a charging port having metal contacts; and

the body-contacting layer of watchband material further comprises a charging port hole;

the flexible circuit board being positioned between the body-contacting layer and outer layer of watchband material such that the charging port overlaps the charging port hole, and the charging port is configured to connect to the battery charger such that the one or more rechargeable battery is recharged.

11. The watchband as recited in claim 1, further comprising one or more rechargeable battery and a battery charger, wherein:

the battery charger is configured to charge the one or more rechargeable battery wirelessly.

12. The watchband as recited in claim 1, wherein:

The one or more rechargeable battery further comprises a buck/boost DC-DC converter configured to regulate the voltage output of the one or more rechargeable battery.

13. The watchband as recited in claim 1, wherein:

The one or more rechargeable battery further comprises a power management circuit configured to regulate the voltage output of the one or rechargeable battery.

14. The watchband as recited in claim 1, wherein:

the first timepiece connection layer of watchband material further comprises a connection channel and a timepiece joint; and

the second timepiece connection layer of watchband material further comprises a connection channel and a timepiece joint;

the timepiece joint of the first timepiece connection layer fitted inside the connection channel of the first timepiece connection layer, and the timepiece joint of the second

## 16

timepiece connection layer fitted inside the connection channel of the second timepiece connection layer.

15. The watchband as recited in claim 1, wherein the flexible circuit board further comprises rigid circuit material and one or more flexible connectors.

16. The watchband as recited in claim 1, wherein the outer layer of watchband material and the body contacting layer of watchband material further comprise a bulged middle.

17. A method of using a watchband with integrated electronics, comprising:

providing a watchband with integrated electronics comprising a body-contacting layer of watchband material; an outer layer of watchband material; a first timepiece connection layer of watchband material; a second timepiece connection layer of watchband material; a flexible circuit board having a microcontroller and a wireless communication device configured to communicate with a mobile device; and a rechargeable battery; wherein the body-contacting layer of watchband material is attached to the outer layer of watchband material such that the flexible circuit, connected to the rechargeable battery, is sandwiched in between the body-contacting layer and the outer layer, and where the first timepiece connection layer and the second timepiece connection layer are attached atop the outer layer at a length sufficient to admit a timepiece;

providing a timepiece;

securing the timepiece between the first timepiece connection layer and the second timepiece connection layer.

18. The method as recited in claim 17, further comprising:

providing an alternate timepiece;

unsecuring and removing the timepiece from the first timepiece connection layer and the second timepiece connection layer;

securing the alternate timepiece between the first timepiece connection layer and the second timepiece connection layer.

19. The method as recited in claim 17, further comprising: communicating data between the microcontroller and the mobile device.
